The water vapour self-continuum absorption was retrieved from experimental high-resolution spectra within 8800 and 10600 cm^{-1} absorption bands. Experimental data were obtained in the Molecular Spectroscopy Facility of the Rutherford Appleton Laboratory (UK) using a Fourier transform spectrometer and a heated multipass absorption cell, as a part of the NERC-EPSRC funded CAVIAR consortium (Continuum Absorption at Visible and Infrared wavelengths and its Atmospheric Relevance) [1]. The water vapour continuum was derived for pure water vapour as the difference between the total optical depth (experimental spectrum) and calculated local water vapour lines contribution using UCL (University College London) compilation [2]. The comparison shows that the retrieved in-band continuum has well-pronounced spectral features (peaks) that are not described by the MT_CKD continuum model [3] (Fig. 1). Similar features were earlier reported within the strongest near-infrared absorption bands and have been attributed to water dimer absorption [4]. The presence of similar peaks within the bands investigated here is reported for the first time.

The experimental part of the work was performed by the NERC-EPSRC funded consortium CAVIAR (UK) [1]; processing and analysis of the experimental data were carried out under support of the Fundamental Research Program II.10.3.8 (Russia).

Figure 1. Comparison of the experimental pure water vapour continuum, retrieved in this work at two temperatures, with the MT_CKD continuum model [3]. Continuum is derived from absorption spectra in pure water vapour at pressure 1000 mbar and path length 17.7 m.
